Communicate data securely

Bookmark this page

In addition to use of encryption, there are options for communicating sensitive data more securely than is possible through use of conventional Internet-based e-mail. For example, the "Tor" system uses multiple computers provided by volunteers in different locations to create greater anonymity and security to e-mail communications. Individual messages are encrypted and re-encrypted multiple times by different computers in the process of transmitting the message to its destination.

This system makes it more difficult for third parties to monitor Internet communications and to access message content. It may be appropriate to use this type of more secure data communications system for particularly sensitive content.
